Evacuation of Area Surrounding Oyster Creek

Location of Oyster Creek

Abstract

The F.D.U. has identified nuclear power facilities as possible targets of terrorism. Oyster Creek is a well-known nuclear power plant in southern New Jersey. The objective of this project is to identify the critical areas surrounding the power plant (10 miles) and calculate the amount of time needed to safely evacuate all of the residents in the event of a terrorist attack. Through the use of Geographic Information System, I have found that it would take a minimum of one hour and ten minutes to successfully evacuate the entire population living within 10 miles of the power plant.

Introduction

Since the tragic events of September 11th, the possibility of further terrorist attacks has haunted the minds of Americans. The Federal Bureau of Investigation has identified nuclear power facilities as possible targets. New Jersey currently has four active nuclear power plants: Hope Creek, Oyster Creek, Salem 1 and 2. The focus of this project is the Oyster Creek plant located in Forsythe River. Oyster Creek is owned by GPU Nuclear Corporation and began operation in 1969. Originally licensed for thirty-five years of operation, Oyster Creek recently applied and received an extension to operate until 2009. The radius of 10 miles has been identified by most nuclear power facilities as a critical area. According to 2000 census data, an estimated 135,000 people live within 10 miles of Oyster Creek.

Objective

Identify the best roads to be used for evacuation in the event of a terrorist attack.

Evacuation routes

Methodology

The location of Oyster Creek was found using aerial photography. Once the plant was located, a point coverage was made by placing a point in the center of the facility. The 10-mile buffer was created using the buffer record found in the "tools" menu bar. The estimated population was found using the coverage "HSG2000." All of the population block within the 10-mile radius were selected and added up to get a total of about 135,000 people. The coverage "spatial" was used to locate all of the roads found in the 10-mile radius. Using Census Feature Class "County," primary roads were identified and selected out to form a new coverage. The calculation for this selection was "all roads not = 44." From there four roads were identified as the best routes for evacuation; these roads are: Garden State Parkway, Route 9, State Highway 72, and Long Branch Blvd. The next step was to find the traffic volume of these roads. Since that information was not available, a calculation was done to find the estimated traffic capacity. The calculation was as follows: Average car = 195, optimal traffic conditions = 5 cars/length. Each car takes up .696 of highway. Speed limit = 55 mph, distance car will go in one hour (8.4). Total time was then divided by 80 (6.4) to get the number of cars that can fit on the road at one time. If the road had 2 lanes the number was doubled. If there were two exits out of the 10-mile radius the total was doubled. For example: Garden State Parkway = 65 miles per hour, 60 * 10500 = 343,000 / 90 = 3,813 cars per hour. 3.813 / 2 = 1,655 cars per hour. The total from each road was then combined to get the total number of cars that can leave the 10-mile radius in one hour. The estimate of four people per car was used to find the amount of people that can be evacuated per hour. The estimated population divided by the total number of people that can be evacuated in one hour equals the amount of time if we were to evacuate the entire population inside the 10-mile radius. The next step was to find suitable shelters for evacuated residents. The coverage "spatialorder" was used to find all of the schools nearest but not inside the 10-mile radius. Five schools were selected: Ocean County College, Toms River East middle school, Toms River East high school, Manchester school and Toms River East high school. Finally, Ocean County was selected out of the coverage "sko" and used as the background on all three of the maps in the layout.

Results

When all of the evacuation roads were added up the total number of cars that can be evacuated in one hour was 26,452 cars. The amount of people that could evacuate in one hour was found to be 113,808 people. The population inside the 10-mile radius was estimated at 135,000 people. It would take one hour and ten minutes, during optimal conditions, to safely evacuate all of the residents inside the 10-mile radius.

Conclusion

I have found that it would take a minimum of one hour and ten minutes to successfully evacuate all of the residents within ten miles of the Oyster Creek nuclear power facility. Though I thought it would take much longer, I still believe that this time is unacceptable. In the event of a terrorist attack or even a meltdown, one hour and ten minutes would not be enough time to escape the critical area without receiving a lethal amount of radiation. Suggested solutions: widen main roads to allow a higher traffic capacity, designate evacuation routes and develop a distribution evacuation plan to all residents living within ten miles of the power plant.
